### 1. Introduction

Search for the ultra high energy gamma rays coming from point sources is one of the main experimental aims of Ohya project (Fig. 1)<sup>1)</sup>. A fast air shower timing system has been constructed at ICRR for the study of the angular resolution of the system and operated approximately half a year. This paper describes the characteristics of the surface array of Ohya "air shower telescope".

### 2. Detail of the System

The array of the 24 channel scintillation counters situated at the campus of ICRR (Tanashi, Tokyo) is shown in Fig. 2. Each scintillator has an area of  $0.25 \text{ m}^2$  and a thickness of 5 cm. The scintillation light is observed by the photomultipliers located at 50 cm above the scintillator. Photomultipliers HAMAMATSU H1161 (R329) are used under a typical high voltage condition  $\sim 1.4 \text{ KV}$ . The output signal from the photomultiplier is sent to the preamplifier Le Croy 612A (gain  $\times 10$ ) via 100 m cable (71B/U). The output pulse height for the single particle is  $\sim 30 \text{ mV}$  and is discriminated by Le Croy 623B. The discriminator out-put signal is then sent to a coincidence circuit 380A. The delay time of the signal from the input of the preamplifier to the out-put of the coincidence circuit is 35 ns.

The out-put of the coincidence circuit is used for the start signal of the TDC 2228A. Meanwhile one of the out-

put signals of each discriminator is delayed by 20 m cable and is used for the stop signal of the time digitizer. The start pulse arrives 15 ns before the stop signal. The time digitizer has a time resolution of 250 ps. The pulse height distribution is also recorded by ADC 2249W. The circuit diagram is shown in Fig. 3.

The linearity of the photomultiplier out-put and the time jittering was investigated by the photo-diode. As shown in Fig. 4, in the 3 decades of the pulse height range ( from 3 mV to 3 V ), the linearity is seen. Typical time jittering of the photomultiplier is given in Fig. 5. For the number of particles  $N_e \geq 10$ , time jittering becomes  $\sim \ln N$  (catalogue value is 0.9 ns ). The jittering of the electronics is less than 250 ps.

### 3. Angular Resolution of the Telescope

The trigger pulse is created when the air shower hits more than any 6 scintillation counters. The number of the fired scintillator is presented by the histogram of Fig. 6. The dotted line represents the data in which (digitizer) point deviates less than 3 standard deviation from the least-square fitting plane.

The air shower front is simply approximated by a plane:  $Z = a X + b Y + C$ . For the vertical shower  $a$  and  $b$  take zero :  $a=b=0$ . The shower with zenith angle less than  $15^\circ$  is only used for the present data analysis. The plane determined by the least-square fitting is obtained by :

Define  $\chi^2 = \frac{1}{2} \sum (Z_i - aX_i - bY_i - c)^2$  and differentiate  $\chi^2$  by  $a, b, c$ . Then we get:

$$\begin{aligned} \sum X_i Z_i &= a \cdot \sum X_i^2 + b \cdot \sum X_i Y_i + c \cdot \sum X_i \\ \sum Y_i Z_i &= a \cdot \sum X_i Y_i + b \cdot \sum Y_i^2 + c \cdot \sum Y_i \\ \sum Z_i &= a \cdot \sum X_i + b \cdot \sum Y_i + c \cdot N \end{aligned}$$

Parameters  $a, b$  and  $c$  are determined by

$$a = |A|/\Delta, \quad b = |B|/\Delta, \quad c = |C|/\Delta \quad \text{and} \quad \Delta = \begin{vmatrix} \sum X_i^2 & \sum X_i Y_i & \sum X_i \\ \sum X_i Y_i & \sum Y_i^2 & \sum Y_i \\ \sum X_i & \sum Y_i & N \end{vmatrix}.$$

The statistical deviations in  $a, b$  and  $c$

$\sigma_a, \sigma_b,$  and  $\sigma_c$  are given by

$$\sigma_a^2 = \sigma^2 [N \sum Y_i^2 - (\sum Y_i)^2] / \Delta, \quad \sigma_b^2 = \sigma^2 [N \sum X_i^2 - (\sum X_i)^2] / \Delta.$$

The angular resolution of the system  $\sqrt{\sigma_\theta^2}$  is defined by  $\sqrt{\sigma_a^2 + \sigma_b^2}$ .

Fig. 7 indicates the distribution of  $\Delta Z_i = Z_i - (aX_i + bY_i + c)$  from the least-square fitting for the data of each scintillator. Fig. 7 shows the fluctuation of shower front  $\sigma_z$  is  $\pm 2.5$  m.

Figs. 8 and 9 represent the distribution of the angular resolution  $\sigma_\theta$  of each shower. Each curve shows when we take the data with  $Z_i \geq 3, 5$ , and the number of total fired scintillators is greater than  $\geq 6, 10, 15$  respectively. From these figures we conclude that our telescope has an angular resolution of  $0.5^\circ$  (at  $1\sigma$ ).

It is interesting to compare present result with the former measurement by Kiel group<sup>2)</sup> with the use of  $1 \text{ m}^2$  scintillators. Their data show on the angular resolution  $1^\circ$ . The data analysis is still continuing for the direction of the Cyg. X-3. The data will be presented at the conference.
